Today's lithium-ion battery, modeled after the Whittingham attempt by, was first developed in 1985. While lithium-ion batteries can be used as a part of a sustainable solution, shifting all fossil fuel-powered devices to lithium-based batteries might not be the Earth's best option. There is no scarcity yet, but it is a natural resource that can be depleted. According to researchers at Volkswagen, there are about 14 million tons of lithium left, which corresponds to 165 times the production volume in 2018. Lithium is extracted on a commercial scale from three principal sources: salt brines, lithium-rich clay, and hard-rock deposits. Each method incurs certain unavoidable environmental disruptions. Salt brine extraction sites are by far the most popular operations for extracting lithium, they are responsible for around 66% of the world's lithium production. The major environmental benefit of brine extraction compared to other extraction methods is that there is very little machinery needed to be used throughout the operation. Whereas hard-rock deposits and lithium-rich clays both require relatively typical mining methods, involving heavy machinery. Despite this...
